What About Idaho Best Flour? We Have it.

CARELESSNESS WILL CAUSE POOR HATCHES

The careful gathering, selecting and holding of hatching eggs are factors too often overlooked, asserts W. H. Allen, poultry specialist at the New Jersey College of Agriculture at New Brunswick. To prove his statement Mr. Allen points out that nearly 90 percent of all eggs that are set in incubators or under hens are fertile, and should hatch strong chicks, yet only 50 to 60 per cept ever do.

Eggs should be collected three or four times a day, and from clean nests. This prevents them from getting and again on the seventh. The eggs chilled, dirty and damp. Grade them for size, color and shape. A bird usually lays eggs of the type of the one from which it was hatched. Keep the eggs in a dry room with a temperature of 50 degrees F., and never hold them more than six days before placing in the incubator. Eggs held 12 days will hatch 10 to 15 per cent fewer chicks than eggs only a week old.

Incubator rooms should not be cold. The ideal temperature is 70 degrees. When the temperature is lower than least 25,000 years and not more than this the liatch will be retarded and 200,000."

the chicks of poor quality. A chick hatched in twenty days is worth two hatched in twenty-two.

Mrs. Earl" Dunham and son, Stewart, came up from Lewiston last week to visit with her sister, Mrs. Louis Alexander. After her visit she will go to Pocatello, where

Why You Should Use an

IOWA Cream Separator

The Separator with the Curved Disc Bowl

Every farm, even if it has only a cow or two should have a modern "IOWA" Cream Separator to handle milk profitably-

The curved disc bowl of the "IOWA" gets more butterfat from a given amount of milk than any other separator. It skims hot milk. COLD milk, sweet or sour milk exhaustively. In numerous official skimming tests it has been conclusively shown to have exceptional efficiency in close skimming. The Jury of Dairy Experts at the last world's fair at San Francisco awarded the "Iowa" first place as outskimming all competing makes.

Prices **\$52.50** and up

Every IOWA Guaranteed for 25 Years

Any part or parts proving defective for any reason will be replaced free of charge within a period of 25 years.

Special Clarifying Chamber

Cream obtained by the Iowa is higher in quality than that obtained by any other separator. The special Clarifying Chamber (patented) removes all the dirt and sediment from the milk before it passes thru separation. With the gravity system and other separators, this sediment, dirt and foreign substances are left in the milk. Not only does this removal of injurious substances give you a more sanitary cream but also because it is free from impurities the cream will keep sweet longer.

Free Automatic Disc Cleaner

The automatic sanitary disc cleaner is furnished free with every "Iowa" making it possible to wash, sterilize and dry all of the curved discs in less than two minutes time.

Make a skimming test of the Iowa on your farm in your own home and prove for yourself that the lowa is the world's closest skimming cream separator. Every lowa cream separator carries John Deere Plow Company's trade mark and warranty.

The CARLSON HARDWARE CO.

The Curved Disc Bowl

Conceded by dairy experts as the World's Closest skimming device.

The common straight disc type of separator can be adapted to any machine. Howeger the Curved Disc Bowl is patented and used only by the Iowa.

Under scientific tests and in actual skimming tests the curved disc will skim closer than the older types of bowls.

Every Iowa disc is made extra strong, of the finest steel and triple tin plated.

The bowl is the heart of a cream separator—why not buy the best?

Community pastures; pastures in which tuberculous cattle are allowed to graze are a source of danger. In most cases the outward appear ance of the animal bears no relation to the degree of infection. The disease frequently develops so slowly that in some cases 14 may be months' or even longer before any symptoms are shown; therefore he on the safe side and have your herd tested.

Cows Require Material for Production of Milk

To keep the summer milk checks up to normal, the cows require a little special attention at this time of the year. In spite of good pastures, grass is apt to be tough and not nearly so appetizing as it was in May or June. Hence the cows are going to stand around in the shade instead of putting sults when fed in connection with other away material for milk production.

feeds. This all means that the cows need a If silage was to be fed alone, and little grain at milking time during the compared with clover and timothy hay late summer months and a little silage, fed alone, there would probably not be very much difference. You would too, if you have it. Green oats and get best results by feeding three peas or green corn are very good, as pounds of slinge a day to one pound well as many other forage crops, cut green and fed during milking time. of hay. Slinge and clover or slinge Here's a good grain mixture to be used while the cows are on pasture: tion.

200 lbs. cornmeal 150 lbs. cottonseed meal 150 lbs. ground oats 150 lbs. gluten feed

Feed the grain mixture according to the way the cow responds. If a cow will not respond to grain feeding in the summer, she isn't worth keeping.

At the New Jersey agricultural experiment station the cows are being sprayed night and morning with a reliable spray that kills the flies. As a result, the cows stand better for milk-

ing and since they are not bothered with the flies they have time to eat their grain. Furthermore, when the milker is swatting flies and the cow is switching her tail around in his face he isn't apt to take much interest in how much milk the cow gives. A good fly spray is a good invest-

ment.

Unprofitable Cows Kept

Simply for Amusement Not over a third of the so-called dairy cows of the United States are profitable to their owners. Ten miltion "loafer" cows are milked whose yield is worth less than their feed. Their owners seem to keep them for the sole purpose of milking them fourteen times a week, cleaning out after them, and otherwise enjoying their soelety.

Making Concrete Blocks

Those situated near a good supply of sand can utilize the winter days profitably in making concrete blocks, posts and other similar products. The new blocks should be protected against freezing for several days. Some of those concrete floors may also be constructed during cold weather, if properly protected.

THE KENDRICK GAZETTE

Suggestions on Proper Meth-.ods to Follow in Mending Damage of Winter.

(Prepared by the United States Department of Agriculture.)

The extensive injury and destruction of trees of all kinds during the winter season has brought many inquiries to the United States Department of Agriculture regarding the proper methods to be followed in repairing the damage done. The following suggestions are made by the department:

Repair Shade and

The first thing that should be done s to remove such large broken branches as are now, or may become, a menace to life and property; this is usually best done by cutting at the point where broken. Attention should then be given to injuries on the main trunk. .If limbs have been split, or partially split, from the main trunk, all splintered wood about the wound should be removed with a sharp gouge and mallet, if not so situated that it can be sawed off. The scar should be smoothed in the manner indicated in Farmers' Bulletin 1178, Tree Surgery, and treated as an open cavity, or as a large surface wound, as the case may necessitate.

Repair Larger Branches.

Attention should next be given to repairing the injuries on the larger last of all to the smaller branches. Sometimes when a limb is broken away the tree is so weakened at the point of breakage that it may again break in a severe wind, and to obviate this the top must be pruned back more or less severely. In case of split crotches, the advice given in Farmers' Bulletin 1178 should be fol lowed regarding the general treatment, including bolting through and above the crack.

In cases of estates where a great amount of injury has occurred, and only a comparatively small force is available for repairing the damage, the final cutting of long stubs can be conveniently left for a time, but wounds or breaks on the main trunk, or close to it, should be attended to promptly, in any case before warm weather arrives.

Leave Cavities Open. It is not necessary to fill cavities. It is better in most cases to leave them open. All final cuts should be immediately covered with some good antiseptic and waterproof paint. It will not be necessary to specially treat the ends of long stubs that are to be removed close to the trunk later in the season.

In no part of repair work should climbing spurs be used on a tree. Spur marks cause inturies through which if is possible for disease and decay germs to enter and cause damage, in some

· FARM **Ornamental Trees** POULTRY PACK EGGS TO SHIP

IN STANDARD CASES

Eggs for shipment should be packed in new standard thirty-dozen cases with new fillers and flats and six excelsior pads. The fillers should weigh not less than 3½ pounds to the set. No claim for breakage will be paid by the express company for eggs packed in second-hand brown tillers. Careful grading, good fillers and good cases will pay. Most breakage is due to the use of bad fillers and poor packing. The use of excelsior pads has reduced breakage 75 per cent.

In packing the eggs first place an excelsior pad in the bottom of the case, then place a filler on this. It will be noted in the honeycomb fillers that two opposite sides of the walls surrounding the eggs are firm and the other two opposite sides are flexible. The sides of the filler that are flexible should run parallel to the sides of the case. This lessens chance for breakage on the cars, since the egg cases are piled in the cars with the sides of the cases parallel to the sides of the car. This method allows the firm part of the filler to hold eggs against the branches in a similar manner, and sudden jars caused by stopping and starting of the train. Place the eggs in this filler with the small ends down,

imbedding themselves in the excelsior pad. On top of the first layer of eggs place a flat followed by a filler, again placing eggs small ends down. Pack the third and fourth layers the same as the second. Directly on the fourth layer place another excelsior pad, packing the fifth layer of eggs directly on this pad, in the same manner as the first layer. On this top layer place another excelsior pad. The cover should be nailed on with five threepenny large-headed nails at each end, but none in the middle. This leaves

absorbs shocks, yet holding the con-At each end of the case place a tag

Turkey Success Depends

Greatly on Free Range "Turkeys cannot be raised in brooders nor in the back yard with chickens," says H. B. Landsen of the University of Arkansas extension service. "Turkey hens are more successful with young turkeys than are chicken hens. Let them forage all they wish. They require some wild variety of feed which they find when at liberty.

"The dread disease known as black head destroys more than 60 per cent cases more severe than would have of all turkeys hatched," says Land-"The only preventive and remedy that has been discovered so far the turkeys when they are two or three weeks old, giving a teaspoonful of powdered ipecac to each unit of ten turkeys, twice a week, until they are ten weeks old. Those visibly sick may be treated fairly successfully with five drops of tincture ipecac three times a day, but sick birds should be removed from the flock while being

Bad Business to Use Weevilly Bean Seed

Even If Cleaned Good Crop Cannot Be Produced.

Don't plant beans which have been infested with the bean weevil, is the advice of the New York College of Agriculture at Ithaca, which points

out that even if the beans have been cleaned of the living weevils by fumigation, the percentage of germination is likely to be low and the plants which do come up may be weak.

The college authorities say that infestation by the bean weevil may take place either in the field or in the bin. With the pea weevil, infestation occurs only in the field.

To destroy the weevils, the beans should be fumigated with carbon bisulphide in the fall. It is best to use a very tight box or barrel, tightly covered.

From one-half to one ounce of carbon bisulphide for each bushel of beans will be needed. The liquid should be placed in some shallow dish. such as a pie tin, on top of the beans. The cover should be put on and the fumigation be allowed to continue from 24 to 36 hours, with a temperature of 70 degrees Fahrenheit. The treatment cannot be relied upon at lower temperatures. Carbon bisulphide is very inflammable and should not be brought near a fire.

Tuberculosis Work Goes

Forward Quite Rapidly That the eradication of tuberculosis among cattle herds is going on at a greater rate than ever before is shown by the figure compiled for the past fiscal year by the United States Department of Agriculture. Five states tested more than 200,000 head each, Wisconsin leading with approximately 281,000, followed by Michigan with 274,000, New York with 253,000, Missouri with 219,000, and lows with 214,000.

Leaders in the eradication work believe that it will be necessary to test all cattle in the country before any assurance is possible that the disease can be controlled and eventually eradicated. Investigations indicate that one out of every nine farm premises in the United States harbors one or more tuberculous animals. The lowest record for any state was 1 per cent, or one farm in a hundred, while the highest state percentage was 47.

Reduction Made in Cost

by Using Very Best Seed If farmers had to use the seed generally grown fifty years ago, many of them would be bankrupt and the remainder would be producing crops at 40 per cent greater cost than at the nt time Likewise it would possible to make a further reducti of 15 per cent by using today the ve best seed of varieties known to adapted to our conditions. The statements are based on figures co plled by the Kansas State Agricultur college in which seed such as w used in early days has been comparwith varieties generally grown at t present time.

Alfalfa Is One of Most

Profitable Farm Crops

Where the soll is suitable for alfalfa, it is one of the most profitable crops for the stockman, the diversified farmer, or the cotton farmer, and where possible, every farm should have an alfalfa patch, the size to be governed by the amount of hay and pasturage needed to maintain the live stock kept on the farm. Many have been discouraged because some writer would have one think that its requirements are such as to exclude the average dirt farmer. By following a few simple suggestions any farmer can tell whether his soll is suited to grow alfalfa, and should the soil be suited, he can, by carefully observing a few points, grow it successfully and with profit to himself.

developed from the original simple sen. break. For details of treatment of all scars and wounds send for a copy of is ipecac. As a preventive, begin with Farmers' Bulletin 1178, which can be obtained from the Office of Publications, Department of Agriculture, Washington, D. C.

Remember that prevention is Letter than cure. The open wound of today becomes the decayed spot of next year and the deep rotten cavity of ten years from now. It is better to spend a few days or dollars in careful repair work now than hundreds of dollars for extensive tree surgery

New Disease of Peaches

in 1930.

Discovered in Indiana Purdue university experts are seeking a remedy or prevention for bacterium pruni, a new disease of peaches which has caused much loss in south- but also ground feeds, animal protein, ern Indiana, and are asking orchard-1 ists to be on the lookout for evidences of the diseases in nursery stock. The disease is most pronounced on the leaves, causing irregular, purplish spots and causing the leaves to fall, weakening the tree. On the fruit the disease is in smaller spots but a more decided purplish color, and on the year-old or younger wood it appears purplish brown, often causing slightly raised cankers around the leaf scars. It is thought wind-driven rain spreads the disease. So far no remedy has been found.

Undesirable Flavors or

Odors May Be Prevented Silage odors are absorbed largely through the body of the cow rather than from the air, according to tests made by the United States Department of Agriculture. Rowever, these odors may be practically or entirely removed by the aeration of the milk while it is still warm. Rather heavy feeds of sllage may be given to cows one hour after milking without any undesirable flavors or odors passing into the milk. When green alfalfa was fed in relatively large quantities one hour before milking marked flavors and odors were noticed in the milk, but when as much as 30 pounds per cow was fed after milking there was no effect on the milk from the next milking.

Fotatoes Taste Sweet

The reason for potatoes becoming sweet and disagreeable to the taste is that they have been stored at too low n temperature. Below 40 degrees the stareh in the pointo is converted into sugar, according to John Bushnell, of the Obio experiment station, When this occurs it is only necessary to store then; for a few days at an ordinary room temperature to bring them back to nurmal.

Idaho Cameron.

the wings for the same reason. Tiles or other openings should be made forthe passage of the water so that it will not back up until it can overflow the top. A spillway should be built on the downstream side so that the falling water will not undermine the structure. Concrete Instresses will strengthen it against the great pressure that will be exerted against it. The concrete walls should extend six or more feet into the banks on either side and four feet below the bottom of the ditch. A mixture of the proportions of one sack of portland cement to two cubic feet of sand to three cubic feet of gravel or crushed stone is recommended.

Making Silage of Most

Any Good Green Plants Silage may be made of most any green material, such as sunflowers, clovers, peas, etc., but what is the idea of fooling with these things when common dent corn is much more easily grown, makes more tons per acre, and is the best all-around silage? It seems that sunflowers are used to some extent in some sections, where they do better than corn. The farmer should keep in mind that he can get from 10 to 15 tons per acre when turning corn into silage, and, besides, it is easler to get a good, palatable quality of corn silage than any other kind, and that counts with cows and steers.

bandry division of the United States Department of Agriculture shows. Pasture feeding is also advantageous because of the fertility-added to the soil by the growth of legume hay.

Soy Beans Satisfy

The soy bean seed is a concentrated feed. In digestible crude protein it is about equal to linseed oilmeal. In digestible fat it is about twice as rich as the linseed ollmeal. Few farmers have used the soy beans for feed but those that have are well pleased with the results.

Some Fertilizer Uses

On land that has grown a little low in fertility by overcropping, fertilizer seems to work wonders. The man with a large acreage of wheat cannot, of course, manure more than a small portion of it, spread it thin as he may: but he can use a drill with a fertilizer attachment and cover the whole field.

Makes Excellent Salad Dressings

Quickly, Easily, Economically-and it never curds!

MAYONNAISE

I teaspoon salt 1 egg yolk 1/16 teaspoon cayenne pepper 1 cup Amaizo

2 tablespoons vinegar cr lemon juice

Have utensils and ingredients cold. Put egg yolk and seasoning into shallow dish or into bowl if egg beater is used; mix in about a teaspoon of vinegar or lemon juice; add Amaizo and remaining vinegar, beating until all the vinegar and Amaizo are added. Mayonnaise made with Amaizo thickens quickly and with no danger of separating. A larger quantity of mayonnaise can be made up in this

way by using the same foundation of one egg yolk and adding Amaizo until desired quantity is made. This dressing will be very thick but can be kept covered in a cold place for several days. If it is too'stiff thin with lemon juice or vinegar just before serving.

THOUSAND ISLAND DRESSING

To each cup of Mayonnaise take the following:

2 tablespoons chopped green 1 teaspoon Worcestershire sauce peppers

21/2 tablespoons chopped pimientoes 1 teaspoon onion juice

1 tablespoon tomato catsup 2 tablespoons chili sauce $\frac{1}{2}$ cup whipped cream I hard cooked egg, chopped fine

Mix the first seven ingredients; add salt if necessary; mix thoroughly with the mayonnaise and fold in the whipped cream. Serve ice cold on lettuce or other salad greens or use as cocktail sauce.

results, and it is advisable to do so during late summer, when hot weather has dried up the pasture and reduced the protein content of the grass.

After the calves reach an age of nine to ten months, grain feeding depends entirely upon the condition of the pasture. If it is plentiful, green and succulent, good growth can be obtained without grain. But if it is short and dried up, it should be supplemented by the concentrate feeds.

State Averages of Age

at Which Cows Are Sold (Prepared by the United States Department of Agriculture.)

The average age of milch cows when slaughtered for beef is ten years, and the price realized for such cows is about one-half the price brought by younger cows sold for milking pur-

vestigation of present conditions made this year by the United States Department of Agriculture.

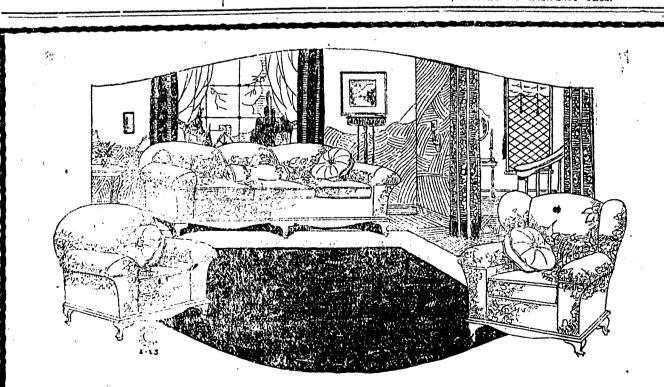

State averages of the age at which cows are sold for slaughter were remarkably uniform, there being no state with an average under nine years and no state with an average over eleven years. States showing an average of eleven years were Maryland, West Virginia, Florida, Wisconsin, Louisiana, Utah and Nevada. States with an average of nine years were New Hampshire, Massachusetts, Connecticut, South Carolina, Georgia and Alabama,

In the early spring this year, when the survey was made, milch cows showed an average sale price of \$32 per head when sold for slaughter, or about 50 per cent of the average price of \$63 for cows sold at the same time for milking purposes.

Production of Progeny The wisest dairyman in the world

cannot tell a prepotent bull by his looks or by his breeding. There is no known way of telling a valuable sire only by his progeny. If his helfers are better producers than their dams he is a good bull-worth his weight in gold, but if his heifers are no improvement over their dams, or if not so good, then he is worthless as a sire.

Who can tell what the result will be when you mate an unknown bull with poor cows? No man can. The most perfect individual, according to standards, might he absolutely worthless, and if his sire was a proved prepotent. bull and his dam had a world's record he might not have this unknown, mysterious power of prepotency. He might transmit undesirable qualities instead of desirable ones.
