KENDRICK, LATAH COUNTY IDAHO, FRIDAY, DECEMBER 7th, 1928

\*\*\*\*\*\* JUST IDAHO By Guy Flenner

\$*\$*\$\$\$\$\$\$\$\$\$\$\$\$\$\$\$\$\$\$\$ JUST IDAHO

Not a few bankers in agricultural communities have had large farming experience, and all of them are naturally concerned in the welfare of agriculture as bearing upon stable and prosperous conditions. More significant, however, is the deep interest of bankers in large centers of population who have had little opportunity for direct contact with the farm and who measure its value to national advancement with the same devices they apply to manufactures, building and other elements of a barometric Several standard lines of farm home folks.

The Christmas Tree

In this state, where the necessity of mountain trees is so universally recognized, not only because of the lumberng industry but on account of the conservation they afford for water, there is an involuntary shudder when we read that annually more than sentiment.

It requires about ten years for which reference is made indicates are well grounded.

Substitutes are offered but few have indicated a willingness to depart from the traditional tree. Idaho's Legislative Hang-Over

There has been an agitation for years in favor of a constitutional amendment providing hold-over members of the senate and house in this state to the end that experience may be the guide from the outset of every

### Craters of the Moon

such as is now going on in the great firepots of the Hawaiian Islands. The high rocky cliffs along the Salmon River are full of evidence that the earth was once a fiery forge. At the Beardsley Hot Springs at Challis there is a terrific whirlpool of rock which appears to have hardened while in violent motion. Along near Riggins similar phenomena

may be seen. Twenty years ago textbooks Mr. and Mrs. E. A. Deobald called Mt. Lassen in California pear asleep rather than dead. Mounds of ashes and dust thrown out of these craters still stand beside the highway.

Looking thoughtfully at these Frank Boyd, proprietor of the things, the tourist may find him-

If it is true the earth was once a sphereof gas and vapor, it was a hundred million years ago. the ball was hundreds of times its present size, its heat beyond tempt to visualize the surface of the inner globe as its metallic elements gradually cooled to liquid form, and its great daily tidal wave of molten mineral Finance: W. J. Carroll, E. H. surged around the ball in the wake of a white-hot moon. When the outer shell of vapor began to turn to poisoned water, a million Entertainment: J. G. Gardner, vears of rainfall of inconceivable volume that never reached the Publicity: E. H. Emery, O. E. real surface was accompanied by thunder and lightening such as the opium eater never dreamed of. Finally it cooled until all the earth was a vast ocean, with here and there a mountain top projecting as an island. These high spots the water started to wear down, depositing sediment in some places five miles thick. Time and effort have never

meant much to Nature. Our craters of the moon have been quiet less than a thousand years. That does not sound like death; that is just a little nap Perhaps in December, 1928, or 2928, there will be a few earthquake rumblings, a big fissure Mr. Fodrea was a newspaper will open up on the mountain Idaho's only national park.

### BUTTER QUALITY CAN BE IMPROVED

The delivery of good cream was never as important as it is today. Reatern markets have often discriminated in price as much as ten cents per pound between butter classing as firsts and that classing as seconds, A slight difference in the score of butter has often made a difference of three cents per pound in the price.

It is impossible to make good butter from poor cream. More attention must be given to the production of good cream on the farm.

Cooling of cream promptly has much to do with the quality. Warm cream should never be mixed with cold cream. It should be cooled before being mixed with other skimmings, otherwire bad flavors and poor quality will result. The best way to cool cream is to place it in cold water. Cream quickly cooled and held in cold water will keep in good condition. Cream should be immediately put in a small can when separated and kept in cold water. Stirring occasionally allows the animal heat to escape and improves the quality. Cream should be in hot weather. If held more than three days it is apt to get moldy Ship every other day if possible.

Every farm does not not have a supply of cold water, but most farms do. A tank so situated that all water pumped for stock purposes runs through the cream tank will serve to keep cream cool. Many manufactured tanks are now on the market which can be purchased; likewise a common barrel may be made to serve the purpose very satisfactorily.

Build a cooling tank on your farm and you will produce less secondgrade cream and thus raise the quality of butter .- Colorado State Dairy Commission.

### Healthy Dairy Herds Are

Always Most Profitable

In a preliminary survey of pure-bred herds in three localities, but one herd has been found free from the disease. This owner has been very particular about purchasing breeding stock. Bulls are bought only subject to abortion test as well as the tuberculin test. The value of clean herds is becoming thoroughly appreciated each year, and breeders of pure-bred cattle who bes lieve their herds free from infection should attempt to confirm this suspicion by blood testing.

The advantages of clean herds are well known. First of all and most important, health herds are more profitable. Abortion disease control is thus a business proposition for every herd owner. Breeders who protect their customers against this infection by selling clean animals are building on a sound basis. On the other hand, prospective purchasers cannot afford to invest in pure-bred animals that harbor abortion infection.

### Home-Raised Calves Are

Best for Replacements

There are two principal reasons why most dairymen prefer to raise the cattle that are needed for their herd replacements. One is a question of economy and the other is that of disease control and elimination. Both are important considerations for practical dairymen.

Often when people depend upon purchasing the mature cows needed in their herds they find that they are forced to take cows that are not entirely desirable. Sometimes the cows are hard to milk, sometimes buyers find a bad quarter after the cow comes fresh and sometimes the cows are not as heavy milkers as expected.

Disease control ; one of the hazards of dairying. This applies to contagious abortion as well as to tuberculosis. Present tests indicate that tuberculosis is more easily eradicated than abortion. When cattle are imported they should be purchased under a sixty-day retest for tuberculosis.

### \*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*

### Dairy Notes

Be careful not to overfeed.

Provide plenty of pure, fresh water.

Keep cows comfortable and content-

Feed cows sparingly the first few

days after calving. Cows should receive grain in pro-

portion to production.

If you have ten or more dairy cows or are feeding heef cattle you need a silo. Silos pay for themselves quickly.

Be prepared to treat an attack of milk fever by having a clean sterilized | while timothy and other similar roughpump to inflate udder with air.

Protect cows from heat and flies by giving them shade and keeping them in darkened stables during the heat of the day.

Successful operation of a milking machine depends largely on the operator. Occasionally there is dissatisfaction with a machine, due to difficulty encountered in meeting bacteria the farmer's attention until after the requirements in milk.

## Black Currant

Spreading Deadly Blister Rust of White Pine.

(Prepared by the United States Department of Agriculture.) Destroy a penny and save six dol-

That is substantially the advice of Samuel B. Detwiler in a pamphlet, "Black Current Spreads White Pine Blister Rust," just published for free distribution by the United States Department of Agriculture.

Mr. Detwiler estimates that if each European black current bush in the United States is worth \$1.25, which he thinks an accessive valuation, the total value would be less than \$900,-000. The value of the merchantable white pine is approximately \$550,000,-000, or 600 times as great. The black current is a deadly enemy of the white pine, and a constant agency in spreading the deadly blister rust.

Similar to Black Stem Rust.

The blister rust of white pine is. similar to black stem rust of wheat in that the fungous disease in each case lives alternately on a valuable plant and then on a nurse plant. Wheat rust is not transmitted without the nursing service of the common delivered to the creamery frequently | barberry. Blister rust on the white | pine does not go from tree to tree. The spores of the disease go from the pine to a current or gooseberry plant, and these serve as sources of infection to the pines.

Careful study of the disease by pathologists of the bureau of plant industry has revealed the peculiar susceptibility of the European black currant. The more familiar currants and gooseberries do not contract the disease over great distances and cannot infect pines at a distance of much more than 900 or possibly 1,500 feet. But instances are known in which the black current has contracted the infection at a distance of 110 miles from the nearest blister rusted pine. The European black current then becomes a source of infection for common currants and gooseberries, and is able to infect pines a mile away. The common currants and gooseberries, in turn, may infect trees within the 900foot zone, or other plants of their kind within the area.

Mr. Detwiler states that the European black current is so susceptible to the white pine blister rust and consequently effective in the rapid spread and establishment of the disease, that the United States Department of Agriculture recognizes the cultivated black current as a distinct menace to the white-pine timber supply of the country.

### A Public Nuisance.

"It is so serious a danger to the production of white-pine timber as to make this kind of current a pub nuisance in all states where white (five-needled) pines grow. The department advises against the growing of this species of current (Ribes nigrum L.) anywhere in the United States and recommends that state authorities, nurserymen and growers take active steps to accomplish its prompt elimination from the Pacific, Rocky Mountain, Atlantic, Appalachi-

an, Ohio Valley, Upper Mississippi Valley and Lake states. The growing of cultivated black currents in home gardens, as well as in nurseries and commercial plantings, should be entirely abandoned throughout these states, because of the great importance of white pines and the relatively small value of black currents."

Miscellaneous Publication 27-M is a revision with added illustrations of an article Mr. Detwiler contributed to the current Yearbook of the Department. It is available for free distribution on request to the Department of Agriculture, Washington,

### \*\*\*\* Agricultural Hints \*\*\*\*

Soy beans should be cut for hay just when the leaves begin to turn yellow.

Sweet clover should be grazed so closely that stock eat the new, tender shoots all the time, or it will get

tough.

One of the essentials of a good silo is an impervious wall, one which will exclude air and retain the moisture in the silage.

If certain interests can afford to spend a million dollars to oppose cooperative marketing, what must it be worth to the farmers?

A few rods of woven wire fencing will make a good insurance policy for the garden, protecting it against the vigorous attacks of poultry and live

Clover, alfalfa, soy beans and all other legumes add nitrogen to the soil, age crops remove large quantities of this element from the soil. The latter tear down the soil; the former build it up.

The control of forage-crop insects must differ fundamentally from the control of the insects of the orchard and garden. Much of the loss to forage crops is caused by insects that work in the soil, where they rarely attract harm is done.

## The NEW KENDRICK THEATRE

More Than One Culling

Is Essential in Year

Culling hens is the process of removing from the flock the undesirable, the object being to increase the average egg production of the flock and to retain for breeding purposes those hens which possess superior qualities. While the term culling is usually applied to hens during their laying period, successful poultrymen are constantly employing a system of cuiling, including the eggs selected for incubation, the young stock at broiler size. the pullets just before they go into their winter laying quarters, and the males used as breeders. The greatest emphasis in the past has been placed on the laying flock on the basis that the best producers in the past will naturally be the best producers in the

The first requirement for successful culling is the treatment of the flock prior to the culling process. Obviously good hens will appear as culls if they have not received proper rations or care. The most expert will be helpless in determining the relative value 1

of various hens unless the hens have been fed satisfactory laying rations in adequate amounts.

### Sun Saps Pep

Exposure to the sun turns white plumage yellow, bleaches yellow and built plumage, robs black feathers of their luster and turns them brown. The sun which puts life into chickens. if given in continuous doses saps their pep and stunts their growth. Ducks suffer even more. Poults wilt. Whether it be a shelter of branches or burlap, or the living shade of bushes and trees, give the poultry a hiding place from the hot sun during the summer

### Same Old Human Nature

### DAIRY COWS ARE ROUGHAGE EATERS

Certain writers on economic problems state that in the future farm animals must more and more depend on roughage and the by-products of grain that are not suitable for human food. They say that this necessity will arise to supply food for the rapidly increasing numbers in the world's population. Whether this condition ever does come or not, we do know that the grain is the expensive part of the cow's ration, and the more nearly roughage can be made to supply the feed, the cheaper will milk and milk products be produced, writes W. H. Woodley, extension dairyman, college of agriculture. University of Arkansas. Grains, high in protein content, are especially ex-

The farmer is fortunate in that he can raise a roughage that is high in protein and supply this much needed milk producing element in hay cheaper than he can buy it in grain. There is probably no section where some kind of legume hay cannot be raised. An acre of land that will produce two tons of soy bean hay yields three times the digestible protein that the same acre will produce in corn (ears and stover) and five times more than prairie or other grass hays can be raised. It yields about the same amount of total digestible nutrients as the acre of corn, and twice the amount in prairie or grass hay. So to the cow it is both hay and grain.

The milk cow with her, four stom achs and her ability to consume about five times as much feed as the horse, is essentially a roughage animal, and can only do her best work, and do it most economically when she is supplied with all the roughage such as mentioned above, that she will con-

A farmer can buy good grain in the market and the kind that he wants, but even if it was as economic to do so, he can seldom find hay of the quality and kind that it is best to feed, so in self-defense he must raise it.

#### Homemade Fly Spray Is Beneficial in Summer

Most owners of small herds will prefer to buy a prepared fly spray, but others prefer to mix their own. The following ingredients can be purchased at any good drug store and have been used successfully by the Iowa experiment station:

Coal-tar dip, 41/2 quarts; fish oil, 41/2 quarts; coal oil, 3 quarts; whale oil, 3 quarts; oil of tar, 1½ quarts; laundry soap, 3 bars.

In preparing the spray, the three bars of soap should be dissolved in warm water. Then the other ingredients can be added separately and enough water added to bring the total amount up to thirty gallons.

This spray, like others, is most effective for a few hours after using. It has a pronounced odor which aids it as a fly repellant, but it does not seem to affect the milk unless some drops in the utensils. The oil in the spray collects dirt but most of this will wash out when the cows are out in the rain.

### Lack of Proper Feeding

Accountable for Losses There is plenty of good authority. for the statement that one-third of our dairy cows are unprofitable, onethird just about break even and the remaining third only are profitable. The situation is accountable in two ways. First, there is lack of proper feeding. A dairy cow must have a properly balanced ration in order to do her best. Second, there are dairy cows whose breeding is such that they can never be made into profitable producers, no matter how they are fed. Just a glance at some cows will tell any person that they will never be suitable for profitable dairy production, but there are large numbers of the in-between kind that can only be told after they have been tested and fed properly.

### Cut Dairy Heifer Cost

by Reducing Protein That tremendous saving in the cost of raising dairy heifers can be made by reducing the amount of protein in the ration heretofore considered the minimum amount necessary for normal growth, has been shown by 12 years of investigation at the Missouri College of Agriculture. Former standards for the minimum amount of proteln are really 20 to 60 per cent too high, according to the tests. As protein is the most expensive part of the ration and is usually the part that must be purchased, a tremendous saving can be made on the \$400,000,000 required annually to maintain the present cow population.

### Improvement Material

Assuredly, pure-bred bulls must come from an ancestry that has proved to be stronger in production than the grade herds into which they are going. The fact that there were more grade herds in the Iowa cowtesting list than there were pure-bred herds does not prove that farmers must cease to look to pure breds for herd improvement material, however. In the first place, the highest producing pure-bred herds are seldom put on test in cow-testing associations.

FEED AND CARE ARE NECESSARY

To get good summer egg production it is necessary to feed and care for hens even more carefully than in the winter time, in the opinion of Charles N. Keen of the Colorado Agricultural college. Poultrymen are mistaken if they think that just because they have good range for their laying flock they can do away with the mash and scratch feed.

"Experiments have shown that pest results are obtained when the consumption of laying mash is increased and scratch feed decreased during the summer months," says Keen. "It is a good practice when the hens begin to let up in production to moisten enough of the fine much from the feed heppers to last the hens about twenty minutes. Feed this at noon each day. This practice will increase the consumption of protein-carrying mash so essential for egg production. During the winter months more scratch feed is necessary to keep up body weight and provide warmth. In summer, heat is not essential and if hens get too much fattening feed they simply cease

laying and put on weight." By this method the total feed consumption will be less while the birds are on range than when they are confined to their laying houses. Production should, however, remain about the same and will be more economical.

Other factors that will help get economical production during the summer months and also hold up the profits are proper sanitation, careful culling and management. Naturally the death loss will be higher during the hot weather and all sickly birds should be removed from the flock as soon as noticed. Sanitation is also much more of a problem during hot weather, but it is necessary for profits.

"Trying to force an early molt is a mistake," according to Keen. It has not been found practical. Get all the eggs you can while you can, he advises, and if you have good birds which continue to lay through the molt, they should be forced to rest before the hatching season opens the following spring.

### Clean Out Mites and

Bedbugs in Henhouse

Chicken mites and bedbugs in poultry houses can be cleaned out by a thorough application of carbolineum painted on the roosts, dropping boards and in the nests. Gas drippings, obtained from around city gas plants, of mites, according to Iowa State col-

Mites do their work at night, sucking the blood from the poultry. During the day they hide away in small cracks and crevices of the house. In getting rid of mites it is important that all equipment be movable so that it can be cleaned and treated for

In using either carbolineum or gas drippings it is important that the chickens be kept out of the house for 24 hours, as the fumes are likely to injure the chickens' eyes and may taint the eggs.

### Poultry Facts

After the flock has been culled is an excellent time to dip for lice.

Pullets, for heavy winter production, must be well developed, vigorous, and carry a surplus of body fat.

Late molting hens are the laying hens and they should be saved from the market to be used for breeders.

A little ground bone is a good stimulant to pullets that are lazy about laying-also to older hens. But it must be fresh or it may cause ptomaine poisoning.

A sudden change from the regular ration to new grains often causes indizestion and diarrhea. These troubles are frequently confused with other diseases, such as cholera or limber-

Soft-shelled eggs usually are a result of a lack of mineral in the ration. If you place oyster shells or other shell-making materials before your birds, you probably will not be troubled with soft-shelled eggs.

If a cool basement is not available on the farm for storing eggs in summer, a small room may be excavated under the henhouse or dwelling house, or a small structure built after the fashion of a root cellar, with insulated walls and ceiling.

Teach the chicks to roost, as soon as they are old enough to learn. Provide low perches as soon as they are three weeks old, and the chicks won't crowd each other to death in the corners of the brooder house.

A good paint for mites can be made of old engine oil to which is added a small amount of commercial coal tar disinfectant. Paint the roosts on both the upper and under side and soak the oil mixture into the cracks so they will be sealed and leave no space where mites can hide.

### COCCIDIOSIS CAN BE CONTROLLED

Drugs, no matter how impressive their labels, are of no value in controlling coccidiosis, chick disease that is fully as bad as it sounds.

The poultrymen who regularly every spring lose chicks from this disease might better put their faith in inexpensive sanitation methods and the feeding of milk to control coccidiosis, according to extension poultry specialists at the Ohio State univer-

Scientists at the University of California tried these medicines to control coccidiosis: Hydrochloric acid, catechy, a mixture of bichloride of mercury and sulpho-carbolates, potassium dichromate, powdered ipecac and bismuth subnitrate. None of the drugs was effective.

"The disease can be controlled," the Ohio specialists say, "by sanitation and by liberal feeding of milk. The milk helps by producing acidity in the ceca and by stimulating rapid growth. The mash recommended by the University of California is this: Forty pounds of dry skim milk, 10 pounds of wheat bran, 30 pounds of yellow corn meal, 20 pounds of ground

oats or barley. "Start feeding this mash as soon

as the presence of the disease is defermined. Keep the mash constantly before the chicks in hoppers. The essential thing is to get sufficient milk into the chick and to keep the house and surroundings absolutely clean.

"Sick chicks should immediately be separated from healthy ones. Burn the dead ones."

Blanket cow immediately after calving if there is danger that the cow will become chilled.

Remove the afterbirth, if necessary. inside of 48 hours after calving, and do not allow the cow to eat it.

Remove the calf from its mother after the first two to four days and

teach it to drink from a pail.

### HEAVY MILKERS NEED SOME GRAIN

Cows that give a large flow of milk should receive some grain, no mat ter how good the pasture may be. For such cows grain is necessary if the milk flow is to be maintained and the body flesh is to be kept in correct condition. On poor pastures the feeding of grain is not a matter of choice; it is a necessity, if the cows are to do well.

It is impossible to make a grain mixture that will balance pasture grass throughout the entire season. In the early spring, pasture grass contains much more protein than it does later in the season. In hot weather droughts affect the growth of pasture grass, making the use of different grains necessary to properly balance the ration. Corn meal, wheat bran, oats, cottonseed meal, oil meal and gluten feeds are some of the best feeds for cows on pasture. From three to ten pounds of grain daily are the extreme limits usually followed for feeding grain to pastured milk cows, the increase being made gradually as pastures become scant. During very dry weather grass becomes low in succulence; and then is the time to call the summer silo into play. But not all farms are yet equipped with what in time will come to be regarded as a dairying necessity. Therefore the only alternative is to cut and feed some kind of green feed, such as corn. When silage is fed, see that the grain mixture is rich in protein, the ingredient which silage lacks. -Jack Baker in the Dairy Farmer.

### Government Cows Make

Records for Production As a part of the experimental work in dairy-cattle breeding by the bureau of dairy industry, United States Department of Agriculture, production records are kept of all animals in the herds owned and managed by the bureau. These herds are located at Beltsville, Md.; Huntley, Mont.; Ardmore, S. D.; Woodward, Okla., and Iberia, La. Two of the major dairy breeds are represented, namely, Holstein and Jersey.

At least two records are made of each animal, one at an early age and one when mature. Since these projects were started in 1919, a total of 297 official yearly records of purebred cows have been completed. Of these, 190 were made by the 147 Holsteins with an average yearly production per cow of 15,277 pounds of milk and 523 pounds of butterfat at an average age of four years and one month. The 84 head of Jerseys had 107 records with a yearly average of 9,151 pounds of milk and 500 pounds of butter fat per cow at the average age of three years and eleven months.

Bluegrass in pastures is very dependent on a supply of nitrogen for successful growth. This supply is furnished largely by the clovers present. so it is evident that when the clover begins to fail, because of a lack of phosphorus and lime, the bluegrass also begins to fail, because of a lack of nitrogen.

Baby chicks are so tiny and the new brooder house looks so big that before we realize what has happened, the chicks are crowded.

There seems to be direct connection between empty feed hoppers and small eggs as well as in getting them from pullets hatched from small eggs. No matter how clean and fresh these small eggs are they will be graded as number two.

Confine broody hens the first night they stay on the nest. Have a broady coop with a slat or wire bottom, located in a shady place. Have dry mush, milk and water before them and once a day give one ounce of dry mash moistened with milk.

### Wiping 'Em Out

Harry L-' resident here off and on for a number of years, writes he has left town to accept a job elsewhere, but will return in the fall, at which time he will repudiate his just debta dollar for dollar. Alaska Paper

### PROPER TIME TO FATTEN POULTRY

(Prepared by the United States Department of Agriculture.)

Early autumn is the time poultry raisers will usually find advantageous to fatten and dispose of surplus cockerels as well as early hatched pullets of a quality not desired in the flock of winter layers. Market poultry prices are usually highest just before Thanksgiving and Christmas. Another advantage in selling surplus stock fairly early in the season is found in the saving of considerable food ma-

Dr. M. A. Jull, poultry husbandman, United States Department of Agriculture, recommends as a fattening ration a soft mash, measured by weight. composed of corn, four parts; outmeal, two parts; middlings, two parts, and beef scrap, one part. The ground grain should be mixed thoroughly and moistened with sour skim milk or buttermilk. Misk is excellent in fattening mixtures and about two pounds, or a quart, of milk is used to each pound of mash.

Care should be taken not to feed the birds too much during the early part of the fattening period. For the first few days of this diet feed lightly three times a day. For the rest of the period give the birds all they will eat three times a day but do not leave it before them. A four-pound cockerel should add a pound in two weeks. Four pounds of the grain ration may produce a pound gain.

Experienced fatteners sometimes keep poultry on the fattening feed for as long as three weeks; but in most commercial fattening plants the birds are fattened for from seven to ten days. There is often a difference of 5 cents a pound between the market price of thin and plump birds. However, farmers in many parts of the country may not find such advantageous marketing opportunities, and the prices received may not pay for the expense and bother of fattening the birds. In such cases it may prove wisest to sell direct with no attempt to fatten the fowls. Many such birds are bought at the markets by fatteners and conditioned and fattened for

### Culling Undesirable

Hens From the Flock

Culling should be a continuous process from the time the egg is selected until disposition is made of the bird. With the young stock this constitutes removal of unthrifty birds. The pullets should be selected from the standpoint of size, relative rate of maturity, and health. On the other hand, with laying hens, other than the occasional removal of outstanding poor individuals, the ideal time for culling is at the end of the laying season, which runs from July to November. From July on the flock should be examined each month for the purpose of removing the poorer hens. Just how rigid the culling is depends upon the desired reduction of the flock. The later culling enables one to be more exacting in the selection of the superior birds. Obviously it is to the advantage of the poultryman to make more than one culling as he is thereby able to immediately cut down production costs.

### Poultry Notes

If pullets are too slow in starting to lay, give them a wet mash daily for a week or so. That often starts them.

Ground yellow corn, with plenty of milk and a range of rape, clover or alfalfa, will keep the young chicks in good condition.

An effective way of eradicating lice is by means of sodium fluoride. It is easy to apply and inexpensive, and yet how many fail to take advantage of this valuable procedure.

The ventilation problem in the poultry house is much easier to solve if the hens are given enough floor space. Three and one-half square feet of floor space should be allowed for each hen in the flock.

The development of chicks will be checked and hens will stop laying if the common red mites are permitted to grow and develop. In warm weather mites multipl, rapidly.

More than \$15,000,000 are lost each year because of fertile eggs put on the market from June to October. Most of this loss comes from the farms because the male birds are kept until fall or winter. It is the eggs fertilized by these males that rot after they leave the farms, causing heavy losses all along the marketing line.

Good poultry is necessary if there is to be a profit made by keeping it. Specialized farms are becoming more numerous, but for many years to come the main output of eggs and pourry meat will be supplied by the general

Sweet or sour milk seem to give equally good results in chick feeding. When liquid milk is not available on the farm, it pays to buy a milk substitute. Dried buttermilk is a convenient form of milk substitute to use as it can be mixed with the mash.

### Success at Failing

Don't call a man a failure unless you know what he was trying to do. Maybe his ambition was to get by working .-- San Francisco without Chronicie.

#### Growth of Habit

In our habits we are only masters of the beginning: their growth by gradual stages is imperceptible, like the growth of disease - Aristotle

#### Oysters Top List

Oysters are more valuable than any other single product of the fisheries
